COVID-19 crisis causes 17 percent drop in global carbon emissions

Date: May 19, 2020

Source: University of East Anglia

Summary: The COVID-19 global lockdown has had an 'extreme' effect on daily carbon emissions, but it is unlikely to last, according to a new analysis.

The COVID-19 global lockdown has had an "extreme" effect on daily carbon emissions, but it is unlikely to last -- according to a new analysis by an international team of scientists.

The study published in the journal *Nature Climate Change* shows that daily emissions decreased by 17% -- or 17 million tonnes of carbon dioxide -- globally during the peak of the confinement measures in early April compared to mean daily levels in 2019, dropping to levels last observed in 2006.

Emissions from surface transport, such as car journeys, account for almost half (43%) of the decrease in global emissions during peak confinement on April 7. Emissions from industry and from power together account for a further 43% of the decrease in daily global emissions.

Aviation is the economic sector most impacted by the lockdown, but it only accounts for 3% of global emissions, or 10% of the decrease in emissions during the pandemic.

The increase in the use of residential buildings from people working at home only marginally offset the **drop** in emissions from other sectors.

In individual countries, emissions decreased by 26% on average at the peak of their confinement.

The analysis also shows that social responses alone, without increases in wellbeing and/or supporting infrastructure, will not drive the deep and sustained reductions needed to reach net zero emissions.

Prof Corinne Le Quéré of the University of East Anglia, in the UK, led the analysis. She said: "Population confinement has led to drastic changes in energy use and CO₂ emissions. These extreme decreases are likely to be temporary though, as they do not reflect structural changes in the economic, transport, or energy systems.

"The extent to which world leaders consider climate change when planning their economic responses post COVID-19 will influence the global CO₂ emissions paths for decades to come.

"Opportunities exist to make real, durable, changes and be more resilient to future crises, by implementing economic stimulus packages that also help meet climate targets, especially for mobility, which accounts for half the decrease in emissions during confinement.

"For example in cities and suburbs, supporting walking and cycling, and the uptake of electric bikes, is far cheaper and better for wellbeing and air quality than building roads, and it preserves social distancing."

The team analysed government policies on confinement for 69 countries responsible for 97% of global CO₂ emissions. At the peak of the confinement, regions responsible for 89% of global CO₂ emissions were under some level of restriction. Data on activities indicative of how much each economic sector was affected by the pandemic was then used to estimate the change in fossil CO₂ emissions for each day and country from January to April 2020.

The estimated total change in emissions from the pandemic amounts to 1048 million tonnes of carbon dioxide (MtCO₂) until the end of April. Of this, the changes are largest in China where the confinement started, with a decrease of 242 MtCO₂, then in the US (207 MtCO₂), Europe (123 MtCO₂), and India (98 MtCO₂). The total change in the UK for January-April 2020 is an estimated 18 MtCO₂.

The impact of confinement on 2020 annual emissions is projected to be around 4% to 7% compared to 2019, depending on the duration of the lockdown and the extent of the recovery. If pre-pandemic conditions of mobility and economic activity return by mid-June, the decline would be around 4%. If some restrictions remain worldwide until the end of the year, it would be around 7%.

This annual **drop** is comparable to the amount of annual emission reductions needed year-on-year across decades to achieve the climate objectives of UN Paris Agreement.

Prof Rob Jackson of Stanford University and Chair of the Global Carbon Project who co-authored the analysis, added: "The **drop** in emissions is substantial but illustrates the challenge of reaching our Paris climate commitments. We need systemic change through green energy and electric cars, not temporary reductions from enforced behavior."

The authors warn that the rush for economic stimulus packages must not make future emissions higher by delaying New Green Deals or weakening emissions standards.

'Temporary reduction in daily global CO₂ emissions during the COVID-19 forced confinement', Corinne Le Quéré, Robert B. Jackson, Matthew W. Jones, Adam J. P. Smith, Sam Abernethy, Robbie M. Andrew, Anthony J. De-Gol, David R. Willis, Yuli Shan, Josep G. Canadell, Pierre Friedlingstein, Felix Creutzig, Glen P. Peters, is published in *Nature Climate Change* on May 19.

The research received support from the Royal Society, the European Commission projects 4C, VERIFY and CHE, the Gordon and Betty Moore Foundation, and the Australian National Environmental Science Program.
